Alpaka Hackathon Section-II: Heat Equation Solution

PLASMA-PEPSC Workshop on Alpaka and OPENPMD

October 24, 2024

Workshop Schedule

Section - I

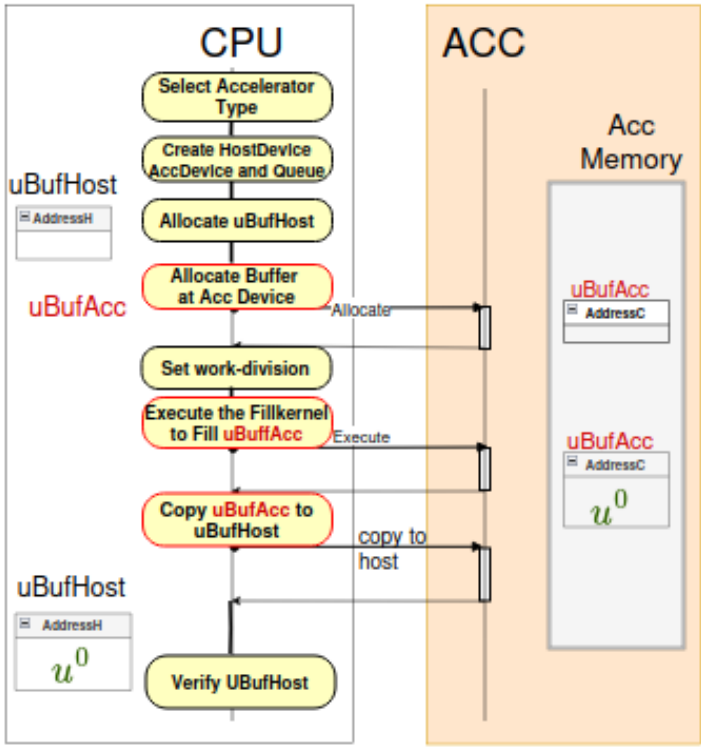
1. Introduction: What is alpaka, where it is used?
2. **Hands on 1**: Installing alpaka and running an example (LUMI)
3. Parallel programming concepts and portable parallelization by alpaka
   - Grid Structure and WorkDivision
   - Data Parallelism
   - Indexing
4. **Hands on 2**: HelloIndex kernel which prints indexes

Section - II

1. Memory management for 1D and 2D data
2. Filling buffers in parallel
3. **Hands on 3**: Kernel to fill initial conditions of heat equation
4. Heat Equation
5. Preparing stencil kernel
6. **Hands on 4**: Heat Equation stencil kernel
7. Programming features and data-structures of alpaka
8. Usability and Optimization
   - Using alpaka mdspan for easier indexing **Hands on 5**
   - Domain Decomposition **Hands on 6** (Day2)
   - Using async queues for performance increase **Hands on 7** (Day2)
   - Using shared memory for performance increase **Hands on 8** (Day2)

Steps of Filling a Buffer in Parallel

1. Select the accelerator
2. Create host-device, acc-device and the queue
3. Allocate host and device memory using Buf and Vec data structures
4. Decide how to parallelize: Set the work-division
5. Create the kernel instance for filling the buffer
6. Execute the kernel
7. Copy the result from Acc (e.g GPU) back to the host buffer.



Allocate memory at Host and at Device

Define number of dim and index type

```
using Dim = alpaka::DimInt<2u>; // Number of dim: 2 as a type
using Idx = std::size_t; // Index type of the threads and buffers
```

Define extents for buffers

```
    // alpaka::Vec is a static array similar to std::array.
    // Dim is a compile-time constant, which is 2.
     constexpr alpaka::Vec<Dim, Idx> numNodes{64, 64};
     constexpr alpaka::Vec<Dim, Idx> haloSize{2, 2};
     constexpr alpaka::Vec<Dim, Idx> extent = numNodes + haloSize;
```

Allocate memories at host and accelerator

```
    // Allocate memory for host-buffer. Creates alpaka::Buf.
    auto uBufHost = alpaka::allocBuf<double, Idx>(devHost, extent);

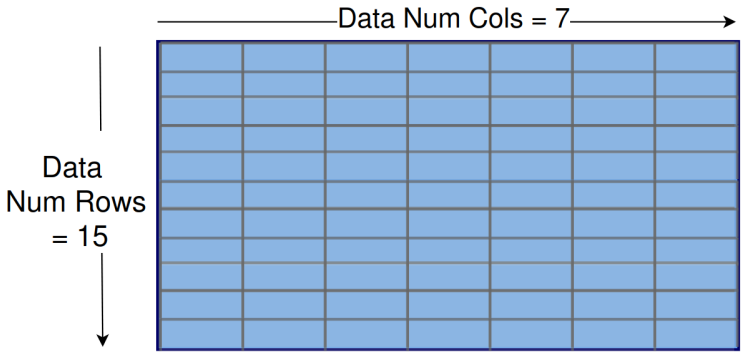
    // Allocate memory for accelerator buffer
    auto uBufAcc = alpaka::allocBuf<double, Idx>(devAcc, extent);
```

Pass acc pointer uBufAcc to kernel and execute kernel

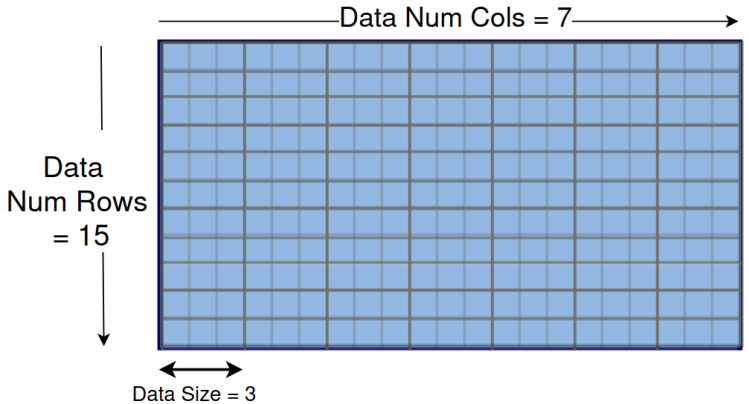
```
alpaka::exec<Acc>(queue, workDiv, initBufKernel, uBufAcc.data(), ...);
```

Aim: Finding the adress of a data and fill it with a specific value

Lets assume that the 2D data is a 15 rows x 7 columns matrix

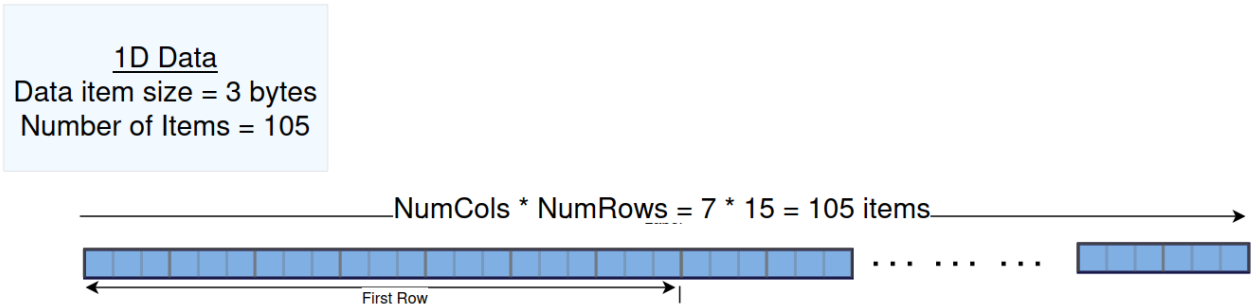


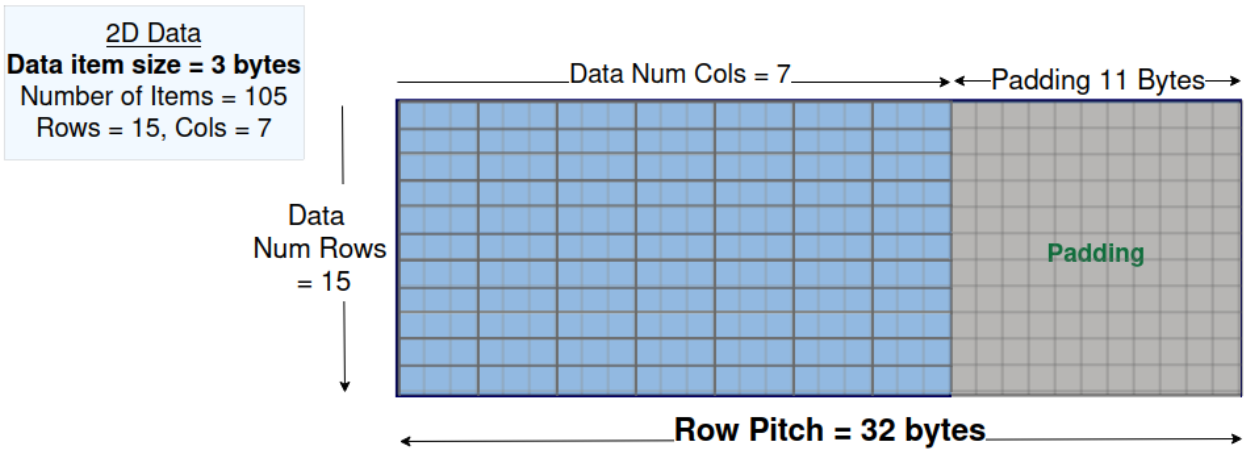
Assume that data-size is 3



Structure of allocated data at the memory

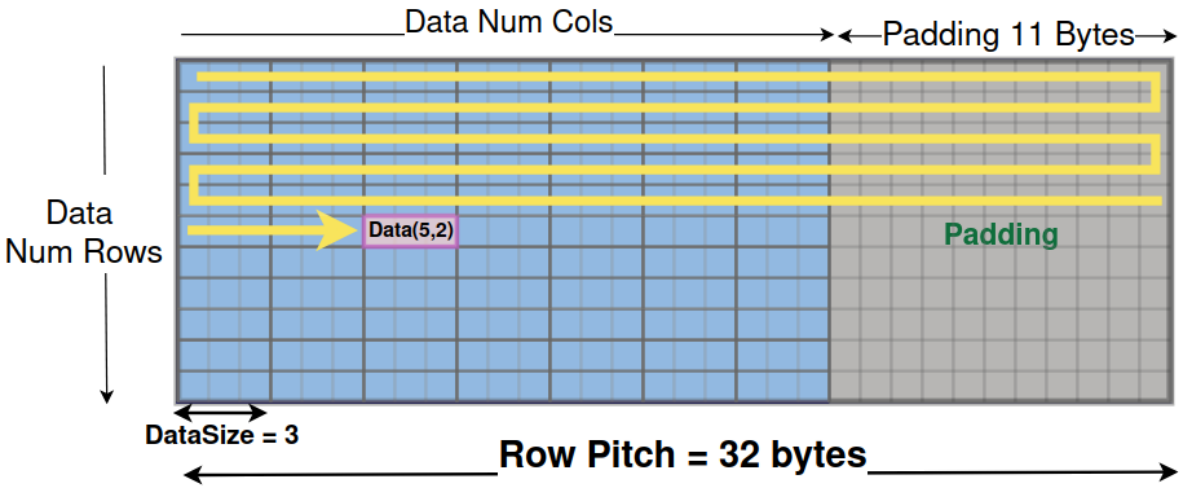
To fill the acc data buffer at the kernel the allocated memory structure should be known.





How to access data given the pointer and the pitch?

How to access data at index (5,2) given the pointer ptr and pitch?
pitch = {32bytes,3 bytes} as {row-pitch, datasize}



```
dataPosition = (char *)ptr+ 5*pitch[0]+2*pich[1]
dataPosition = (char *)ptr+ 5*32+2*3
dataPtr = (T *)dataPosition
// shorter alternative if pitch[0] is divisible by pitch[1];
// which is the usual case
dataPtr = ptr + (5*pitch[0]*2*pitch[1])/sizeof(T)
```

Passing multi dimensional buffer to the kernel

- **Pass 3 variables for a buffer: pointer, "row-pitch", and datasize**

  If a pointer of a 2D buffer is passed to the kernel as a pointer; 2 additional values **pitch** and item **data-size** should also be passed.

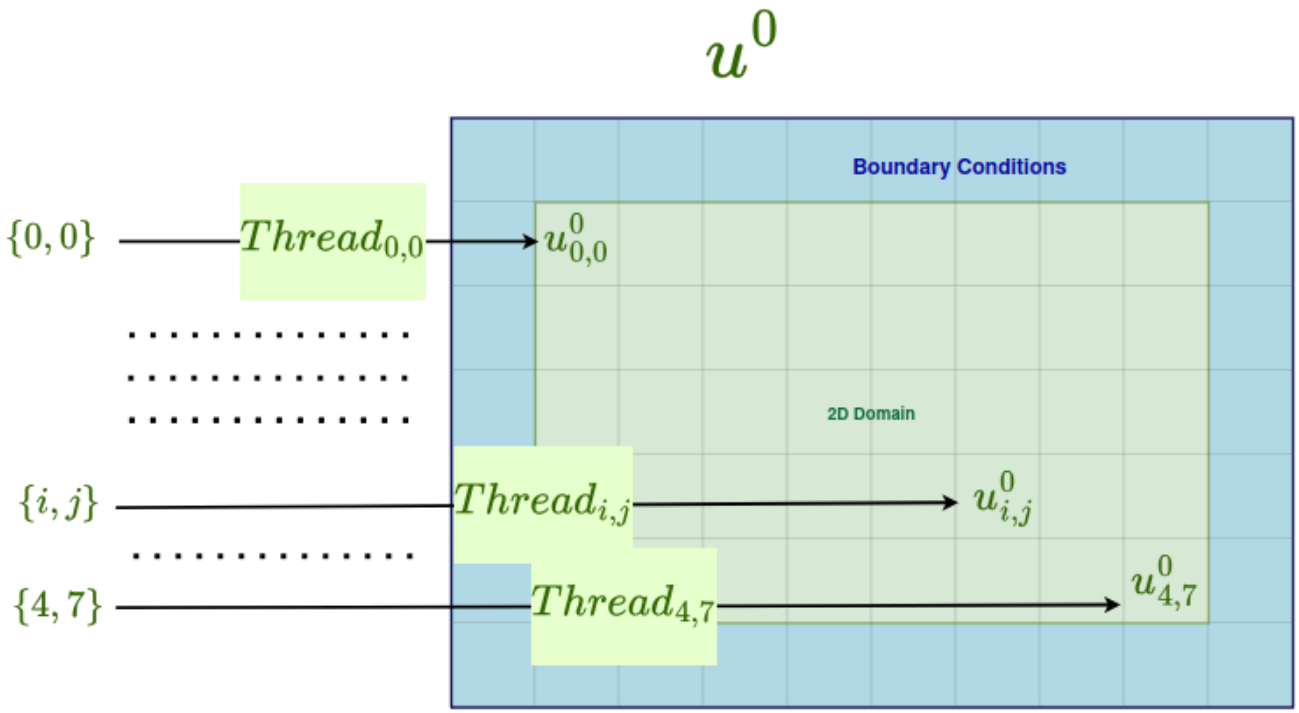
```
1    // Signature of function operator of the Kernel
2    template<typename TAcc, typename TDim, typename TIdx>
3    ALPAKA_FN_ACC auto operator()(
4        TAcc const& acc,
5        double* const bufData,
6        // 2 variables row-pitch and data-type size
7        alpaka::Vec<TDim, TIdx> const pitch,
8        double dx,
9        double dy) const -> void
```

- **Simple Alternative:** Pass an **alpaka mdspan** object

```
1    template<typename TAcc, typename TDim, typename TIdx, typename TMdSpan>
2    ALPAKA_FN_ACC auto operator()(
3        TAcc const& acc,
4        TMdSpan uAccMdSpan
5        ...) const -> void
```

The Kernel to Initialize Heat Values

Calculate and set initial heat values, the u^0 matrix, by running a grid of threads.



Hands on 3: The Kernel to Initialize Heat Values

The InitializeBufferKernel fills the given buffer at the accelerator device (e.g GPU)

Prepare kernel to set initial heat values

- **Thread Index:** Find thread index in the kernel to be used as index to set 2D buffer.
- **Initial Condition at the point:** Find analytically the heat value at the point which has coordinates equal to the 2D thread index.
- **Memory Adress in Buffer:** Calculate the corresponding memory adress in buffer using thread index. Take into account the row-pitch and data-size
- **Set Value at the Adress:** Set the data at the memory position to the calculated initial condition.

```
1   template<typename TAcc, typename TDim, typename TIdx>
2   ALPAKA_FN_ACC auto operator()(
3       TAcc const& acc, double* const bufData,
4       alpaka::Vec<TDim, TIdx> const pitch, double dx, double dy) const -> void {
5   // Get 2D thread index using alpaka index function
6   .....
7   // Calculate analytical solution at point
8   auto heatAtPointValue = analyticalSolution(acc, gridThreadIdx[1] * dx, gridThreadIdx[0] * dy,
        0.0);
9   // Calculate data position in buffer, from thread index and pitches
10  auto ptr = getElementPtr(bufData, gridThreadIdx, pitch);
11  // Set the value using the adress
12  *ptr    = heatPointValue;
13  } // function operator
```

Hands-on Session3: Filling an accelerator buffer paralelly

The Heat Equation

- **The Heat Diffusion over time:**

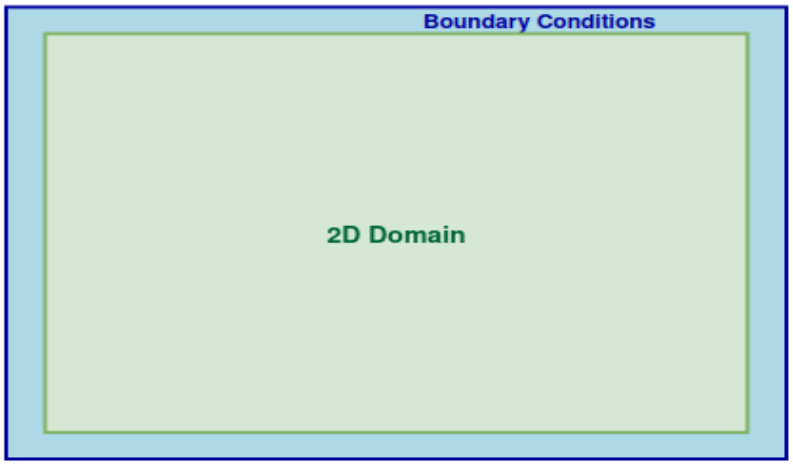
$$\frac{\partial u(x,y,t)}{\partial t} = \alpha \left(\frac{\partial^2 u(x,y,t)}{\partial x^2} + \frac{\partial^2 u(x,y,t)}{\partial y^2} \right)$$

Time and Spatial Derivative Approximations:

$$\left.\frac{\partial u(x,y,t)}{\partial t}\right|_{t=t^n} \approx \frac{u_{i,j}^{n+1} - u_{i,j}^{n}}{\Delta t} \qquad \left.\frac{\partial^2 u(x,y,t)}{\partial x^2}\right|_{x=x_i, y=y_j} \approx \frac{u_{i+1,j}^{n} - 2u_{i,j}^{n} + u_{i-1,j}^{n}}{\Delta x^2}$$

- **Resulting difference equation:**

$$u_{i,j}^{n+1} = u_{i,j}^{n} + \alpha \Delta t \left(\frac{u_{i+1,j}^{n} - 2u_{i,j}^{n} + u_{i-1,j}^{n}}{\Delta x^2} + \frac{u_{i,j+1}^{n} - 2u_{i,j}^{n} + u_{i,j-1}^{n}}{\Delta y^2} \right)$$



The Heat Equation- Cont.

- **The difference equation:**

$$u_{i,j}^{n+1} = u_{i,j}^{n} + \alpha \Delta t \left(\frac{u_{i+1,j}^{n} - 2u_{i,j}^{n} + u_{i-1,j}^{n}}{\Delta x^2} + \frac{u_{i,j+1}^{n} - 2u_{i,j}^{n} + u_{i,j-1}^{n}}{\Delta y^2} \right)$$

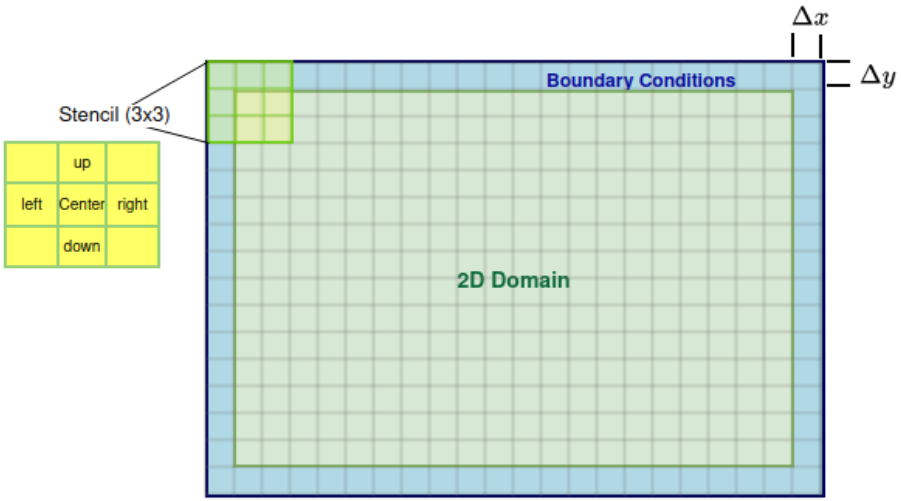
- **Substitute:** $\alpha = 1$, $r_X = \frac{\Delta t}{\Delta x^2}$, $r_Y = \frac{\Delta t}{\Delta y^2}$. **Then** $u_{i,j}^{n+1}$ **is:**

$$u_{i,j}^{n+1} = u_{i,j}^{n} + r_X \left(u_{i+1,j}^{n} - 2u_{i,j}^{n} + u_{i-1,j}^{n} \right) + r_Y \left(u_{i,j+1}^{n} - 2u_{i,j}^{n} + u_{i,j-1}^{n} \right)$$

By regrouping the terms related to $u_{i,j}^{n}$, the equation can be rewritten as:

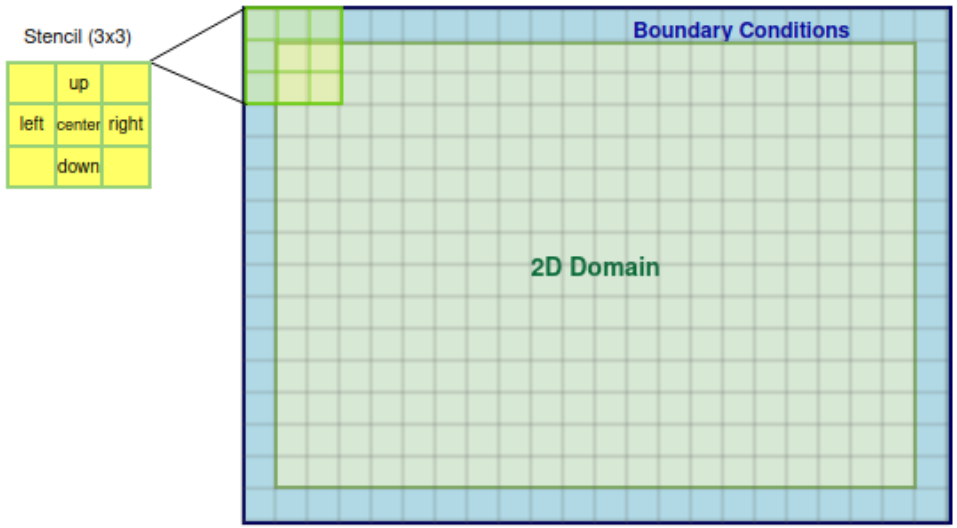
$$u_{i,j}^{n+1} = u_{i,j}^{n} \left(1 - 2r_X - 2r_Y\right) + r_X \left(u_{i+1,j}^{n} + u_{i-1,j}^{n} \right) + r_Y \left(u_{i,j+1}^{n} + u_{i,j-1}^{n} \right)$$

$$S = \begin{pmatrix} 0 & r_Y & 0 \\ r_X & 1 - 2r_X - 2r_Y & r_X \\ 0 & r_Y & 0 \end{pmatrix}$$



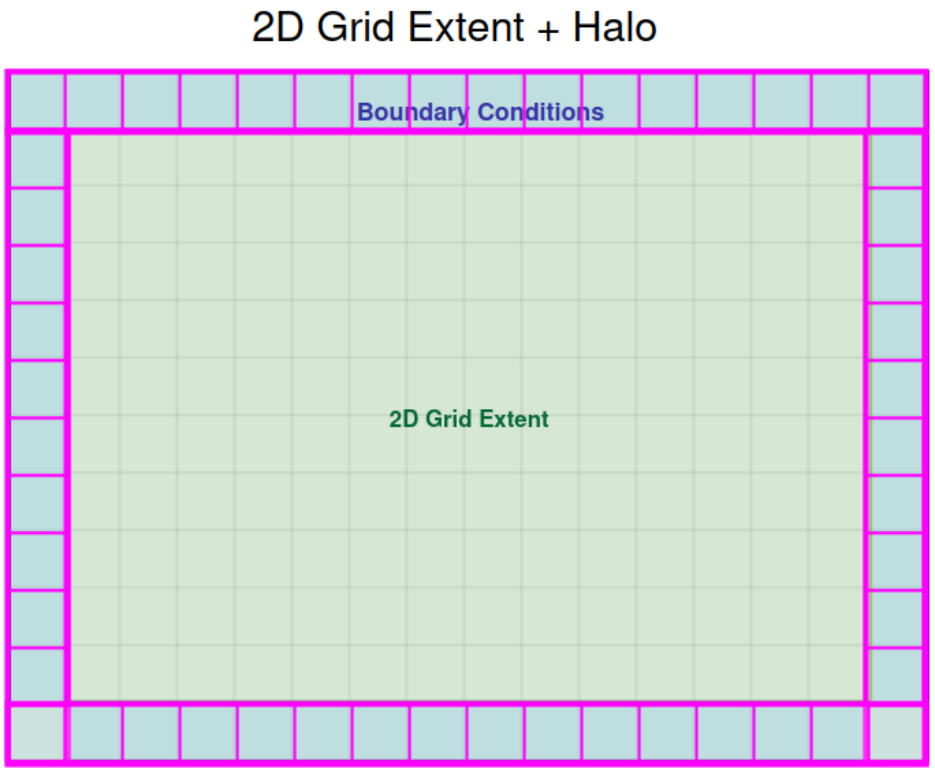
Parallel Heat Equation Solution

- **Data Parallelism:** Each point on the grid can be updated independently based on its neighbors, enabling parallel computation.
- **Independency:** Next values of heat at a point does not depend on previous heat values.
- **Stencil Operations:** Stencil is a core computational pattern in PDE solvers. Updates a grid point in time using its immediate neighbors (left, right, up, down) according to the difference equation.



- **Halo Region for BC:** A layer of grid cells added to the core-domain surrounding the problem domain for Boundary Conditions.

Halo Region

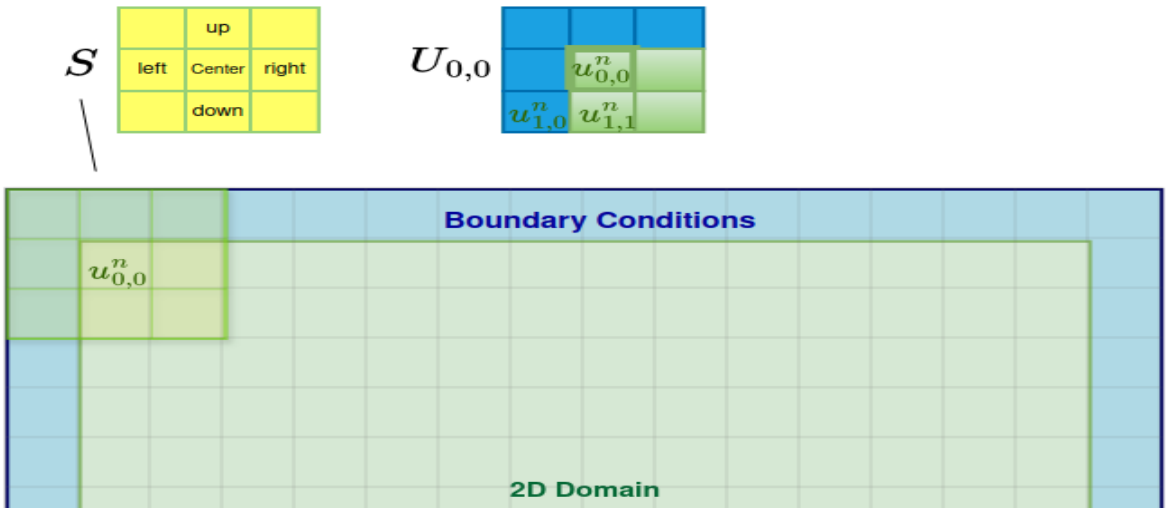


Calculation of $u_{i,j}^{n+1}$ from $u_{i,j}^{n}$

- Kernel execution by thread i, j calculates $u_{i,j}^{n+1}$ using $u_{i,j}^{n}$
- Hence, Each heat point is separately calculated by a thread using **Frobenious Inner Product** (FIP) of S and matrix $U_{i,j}$:

$$u_{i,j}^{n+1} = \langle S, U_{i,j}^{n} \rangle_F = \sum_{m=1}^{M} \sum_{k=1}^{K} s_{m,k} u_{m,k}$$

- S and $U_{0,0}^{n}$ is used by a thread to calculate $u_{0,0}^{n+1}$ using FIP



- Another thread calculates $u_{0,1}^{n+1}$ using S and $U_{0,1}^{n}$

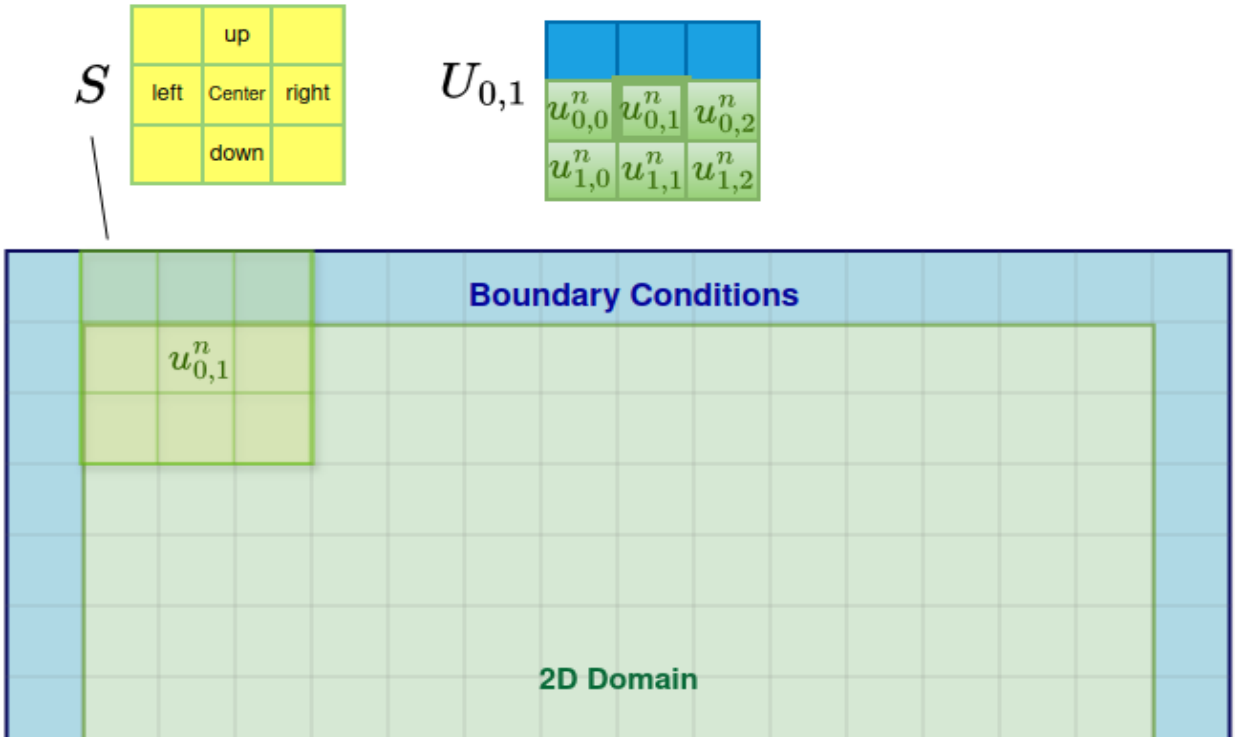


Figure: Another thread calculates $u_{0,1}^{n+1}$

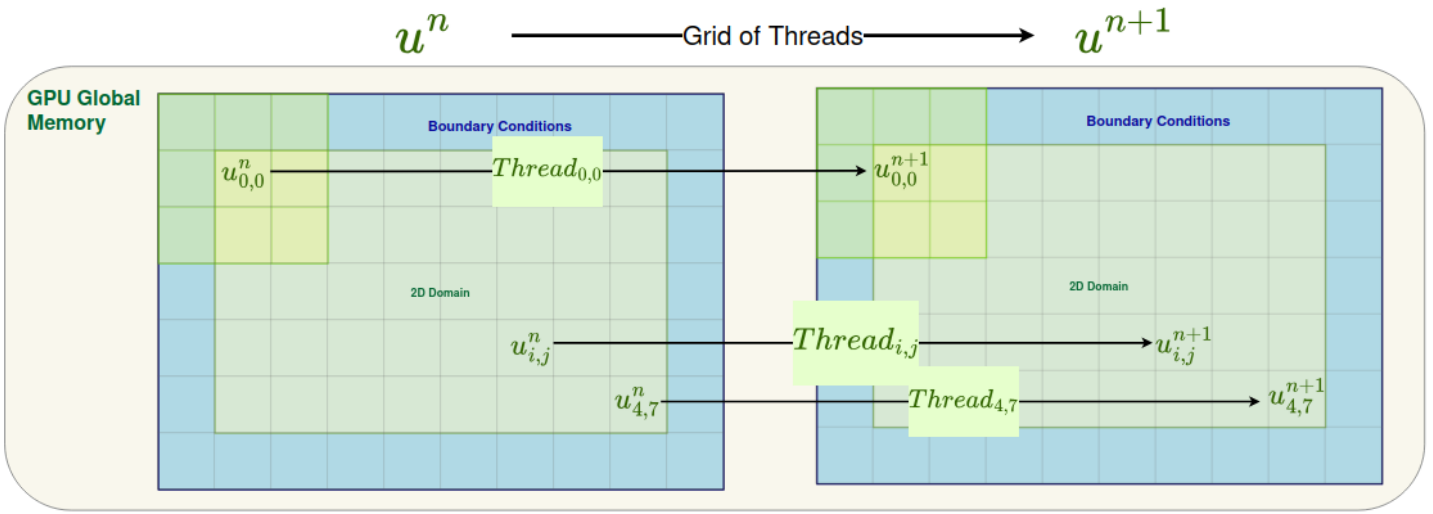
A grid of threads is used to find next 2D heat values

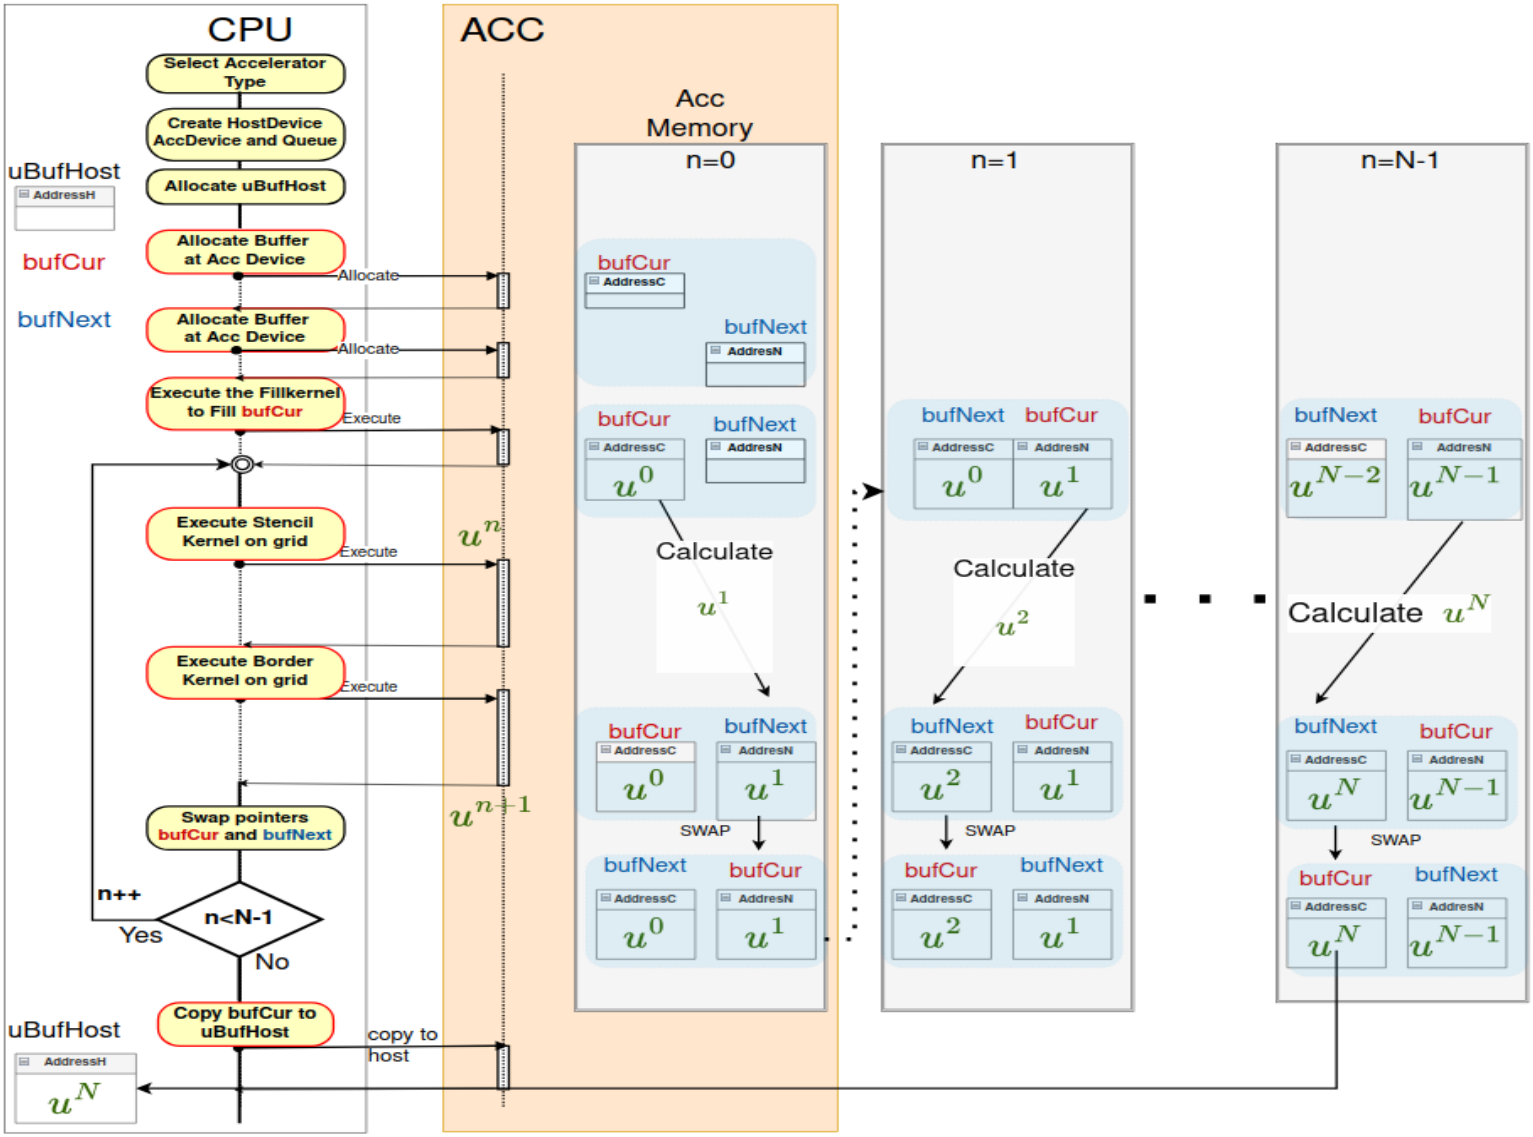


- Stencil kernel will update only core nodes not the border
- The workdiv for stencil-kernel can be calculated by setting grid-thread extent to nodes domain
- The workdiv for the borders-kernel would need larger extents, but will only work on borders of this extended domain.

Complete Heat Equation Solution

- **Initialization:**
  - Define the "host device" and "accelerator device". The "Host" and "Device" in short.
  - Set initial conditions and boundary conditions.
  - Allocate data buffers to host and device.
  - Copy data from host to device buffer to pass to the kernel.
  - Define parallelisation strategy (determine block size).
- **Simulation Loop Over Time:**
  - **Step 1:** Execute `StencilKernel` to calculate next heat values for 2D domain.
  - **Step 2:** Apply boundary conditions using `BoundaryKernel`.
  - **Step 3:** Swap buffers for the next iteration so that calculated $u_{i,j}^{n+1}$ becomes the $u_{i,j}^{n}$ for the next step.
- **Copy result from Acc to Host:**
  - Use alpaka::memcpy to copy latest 2D heat buffer u^n to host back.
- **Validation**

Complete Heat Equation solution



Hands On 4: The Stencil Kernel

What kind of parallelization needed to calculate $u_{i,j}^{n+1}$ using $u_{i,j}^{n}$

- StencilKernel needs a Work-division to work on domain of all nodes (without halo)
- Boundary kernel needs a Workdivision which covers nodes + halo region
- Boundary kernel will only use threads corresponding to halo region

Coding StencilKernel

- **Input:** Check the size of the input buffer, it should include halo region as well
- **Thread Index:** Find thread index in the kernel. This index will be used as the center of 3x3 stencil.
- **Memory Adress in Buffer:** Calculate the corresponding memory adress in buffer using thread index. Take into account pitch and data-size
- **Find Stencil matrix** Use dx, dy, dt to calculate the stencil matrix
- **Calculate new heat value:** Calculate $u_{i,j}^{n+1}$ using **Frobenious Inner Product** of 3x3 matrices
- **Set Value at the Adress:** Set the data at the memory adress.

```
1  struct StencilKernel
2  {
3      template<typename TAcc, typename TDim, typename TIdx>
4      ALPAKA_FN_ACC auto operator()(
5          TAcc const& acc,
6          double const* const uCurrBuf, double* const uNextBuf,
7          alpaka::Vec<TDim, TIdx> const chunkSize,
8          alpaka::Vec<TDim, TIdx> const pitchCurr, alpaka::Vec<TDim, TIdx> const pitchNext,
9          double const dx,double const dy, double const dt) const -> void
10     {
11         ...
12     }
13 };
```

Hands-on Session4: Stencil Kernel to Calculate u^{n+1}

Setting up the stage to run kernels

1. Selecting the accelerator and host devices
2. Allocating and setting host and accelerator device memory
3. Alpaka Vector, Buffer and View
4. Passing data to the accelarator
5. WorkDiv
6. Define Queue

Accelerator, Device and Host

Define number of dim and index type

```
using Dim = alpaka::DimInt<2u>; // Number of dim: 2 as a type
using Idx = std::size_t; // Index type of the threads and buffers
```

Define the accelerator

```
// AccGpuCudaRt, AccGpuHipRt, AccCpuThreads, AccCpuSerial,
// AccCpuOmp2Threads, AccCpuOmp2Blocks, AccCpuTbbBlocks
using Acc = alpaka::AccGpuHipRt<Dim, Idx>;
using DevAcc = alpaka::Dev<Acc>;
```

Select a device from platform of Acc

```
auto const platform = alpaka::Platform<Acc>{};
auto const devAcc = alpaka::getDevByIdx(platform, 0);
```

Select a host and hostype to allocate memory for data

```
// Get the host device for allocating memory on the host.
auto const platformHost = alpaka::PlatformCpu{};
auto const devHost = alpaka::getDevByIdx(platformHost, 0);
// Host device type is needed, still not known
using DevHost = alpaka::DevCpu;
```

What is Accelerator

Accelerator hides hardware specifics behind alpaka's abstract API

- **On Host:** Accelerator is a type. A Meta-parameter for choosing correct physical device and dependent types

```
using Acc = acc::AccGpuHipRt<Dim, Idx>;
```

- **Inside Kernel:** Accelerator is a variable. Contains thread state, provides access to alpaka's device-side API
  - The Accelerator provides the means to access to the indices

```
// get thread index on the grid
auto gridThreadIdx = alpaka::getIdx<Grid, Threads>(acc);
```

  - The Accelerator gives access to alpaka's shared memory (for threads inside the same block)

```
// allocate a variable in block shared static memory
auto& sdata = alpaka::declareSharedVar<double[T_SharedMemSize1D], __COUNTER__>
     acc);
```

  - Enables synchronization on the block level

```
// synchronize all threads within the block
alpaka::syncBlockThreads(acc);
```

  - Maps all device-side functions to their native counterparts

```
alpaka::sqrt(acc, val); // or atomics, create distribution
```

What is alpaka Buffer, Vector and View

- **alpaka::Buf** is multi-dimensional dynamic (runtime sized) container.
  - Contains **memory adress, extent, datatype** and the **device** that memory belongs to!
  - Device to device copy is easy
  - Supports [] operator but not [][].

```
1  // Allocate buffers
2  auto bufCpu = alpaka::allocBuf<float, Idx>(devCpu, extent);
3  auto bufGpu = alpaka::allocBuf<float, Idx>(devGpu, extent);
4  ....
5  // Copy buffer from CPU to GPU. Notice: destination comes first!
6  alpaka::memcpy(gpuQueue, bufGpu, bufCpu);
7  // cuda way: cudaMemcpy(b_d, b_host, sizeof(float)*N, cudaMemcpyHostToDevice)
```

- **alpaka::Vec** is a static 1D array.

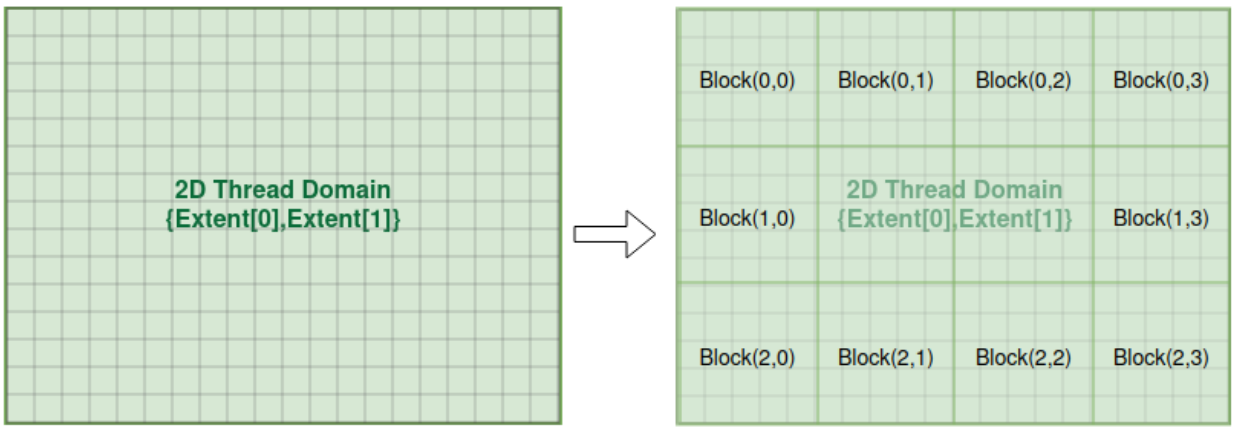
```
1  alpaka::Vec<SizeOfArrayAsType,DataT> myVec;
```

- **alpaka::View** is a non-owning view to an already allocated memory, so that it can be used in alpaka::memcpy

Determining WorkDiv using getValidWorkDiv function

getValidWorkDiv function calculates blocksize using **full grid extent!**

```
1    // All kernel inputs are needed because work-division depends on the kernel
2    InitializeBufferKernel initBufferKernel;
3    // Elements per thread needed to determine work-div
4    constexpr alpaka::Vec<Dim, Idx> elemPerThread{1, 1};
5    // Give full-grid thread extent as input!
6    alpaka::KernelCfg<Acc> const kernelCfg = {extent, elemPerThread};
7    // Determine the work-div using kernel and kernel arguments
8    auto workDiv = alpaka::getValidWorkDiv(kernelCfg, devAcc, initBufferKernel,
         uBufAcc.data(), pitchCurrAcc, dx, dy);
```



Setting WorkDiv Manually: Set 3 vectors of workdiv

```
// Set Dim and Index type
using Idx = uint32_t;
using Dim2D = alpaka::DimInt<2u>; // 2 as a type
// 2-element vectors
alpaka::Vec<Dim2D, Idx> gridBlockExtent{M,N}; // 2D grid
alpaka::Vec<Dim2D, Idx> blockThreadExtent{32,32}; // 2D block
alpaka::Vec<Dim2D, Idx> elementExtentPerThread{1,1};
// MxN blocks each has 32x32 threads, each level is 2D
alpaka::WorkDivMembers<Dim2D, Idx> workdiv2D{gridBlockExtent,
    blockThreadExtent, elementExtentPerThread};
```

```
using Dim1D = alpaka::DimInt<1>;//Set number of dims to 1
using Vec1D = alpaka::Vec<Dim1D, Idx>;//Define alias
auto workDiv1D = alpaka::WorkDivMembers(Vec1D{M},  Vec1D{4u},  Vec1D{1u});
// alternatively
using Dim3D = alpaka::DimInt<3>;//Set number of dims to 3
using Vec3D = alpaka::Vec<Dim3D, Idx>; //Define alias
auto workDiv3D = alpaka::WorkDivMembers(Vec3D{1,1,M},  Vec3D{1,1,4u},  Vec3D{1,1,1u});
```

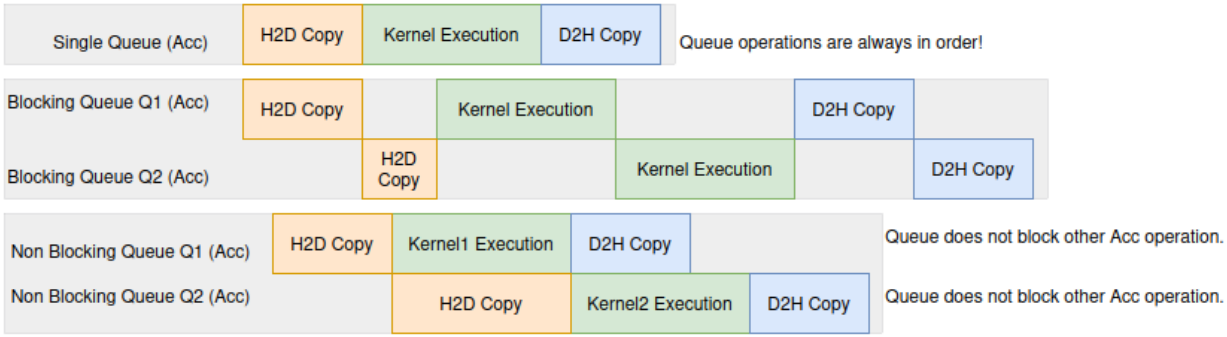
What is alpaka::Queue

- **alpaka::Queue** is "a queue of tasks".
- Used for sycnhronization of tasks like memcpy or kernel-execution
- Queue is always FIFO, everything is sequential (in-order) inside the alpaka::queue
- If the Queue is **non-blocking** the caller(host) is not blocked
- Different non-blocking queues can run in parallel
- Within a single queue accelerator back-ends can be mixed (used in interleaves)

```
1  // Create queue
2  using QueueAcc = alpaka::Queue<Acc, alpaka::NonBlocking>;
3  QueueAcc computeQueue{devAcc};
4  // Copy host -> device, use the queue
5  alpaka::memcpy(computeQueue, uCurrBufAcc, uBufHost);
6  alpaka::wait(computeQueue);  // Not needed, we have single queue
7  // Create kernel instance
8  StencilKernel<sharedMemSize> stencilKernel;
9  // Execute kernel using queue
10 alpaka::exec<Acc>(computeQueue, workDiv_manual, stencilKernel...)
```

Multiple Queues

- Queues are used for synchronization



- Copying and processing data synchronously

```
1  using QueueGpu = alpaka::Queue<AccGpu, alpaka::NonBlocking>;
2  StencilKernel<sharedMemSize> stencilKernel;
3  auto queueGpu1 = QueueGpu{devGpu};
4  auto queueGpu2 = QueueGpu{devGpu};
5  alpaka::memcpy(queueGpu1, uCurrBufAcc, uBufHost);
6  alpaka::wait(QueueGpu1);
7  // Run 2 tasks in parallel: memcpy and exec
8  alpaka::memcpy(queueGpu2, uCurrBufAcc2, uBufHost2);
9  alpaka::exec<Acc>(queueGpu1, workDiv_manual, stencilKernel...)
10 alpaka::wait(QueueGpu1);
11 alpaka::wait(QueueGpu2);
```

Queue Operations and Tasks

- Wrapping an operation as a **task** is possible.

```
auto const taskRunKernel = alpaka::createTaskKernel<Acc>(workDiv,
    kernel, /* kernel args */);
auto const taskMemcpy = alpaka::createTaskMemcpy<Acc>( uCurrBufAcc,
    uBufHost);
```

- Tasks are executed by **enqueue()** function.

```
alpaka::enqueue(queueA, taskMemCopy);
// taskRunKernel starts after taskMemCopy has finished, even queueA is
     non-blocking
alpaka::enqueue(queueA, taskRunKernel);
```

- Wait can be used to make queue finish all tasks enqueued

```
// wait until all tasks have completed
alpaka::wait(queueA);
// block queueA until otherQueue has completed
alpaka::wait(queueA, otherQueue);
```

- Queues can be checked for completion of all tasks

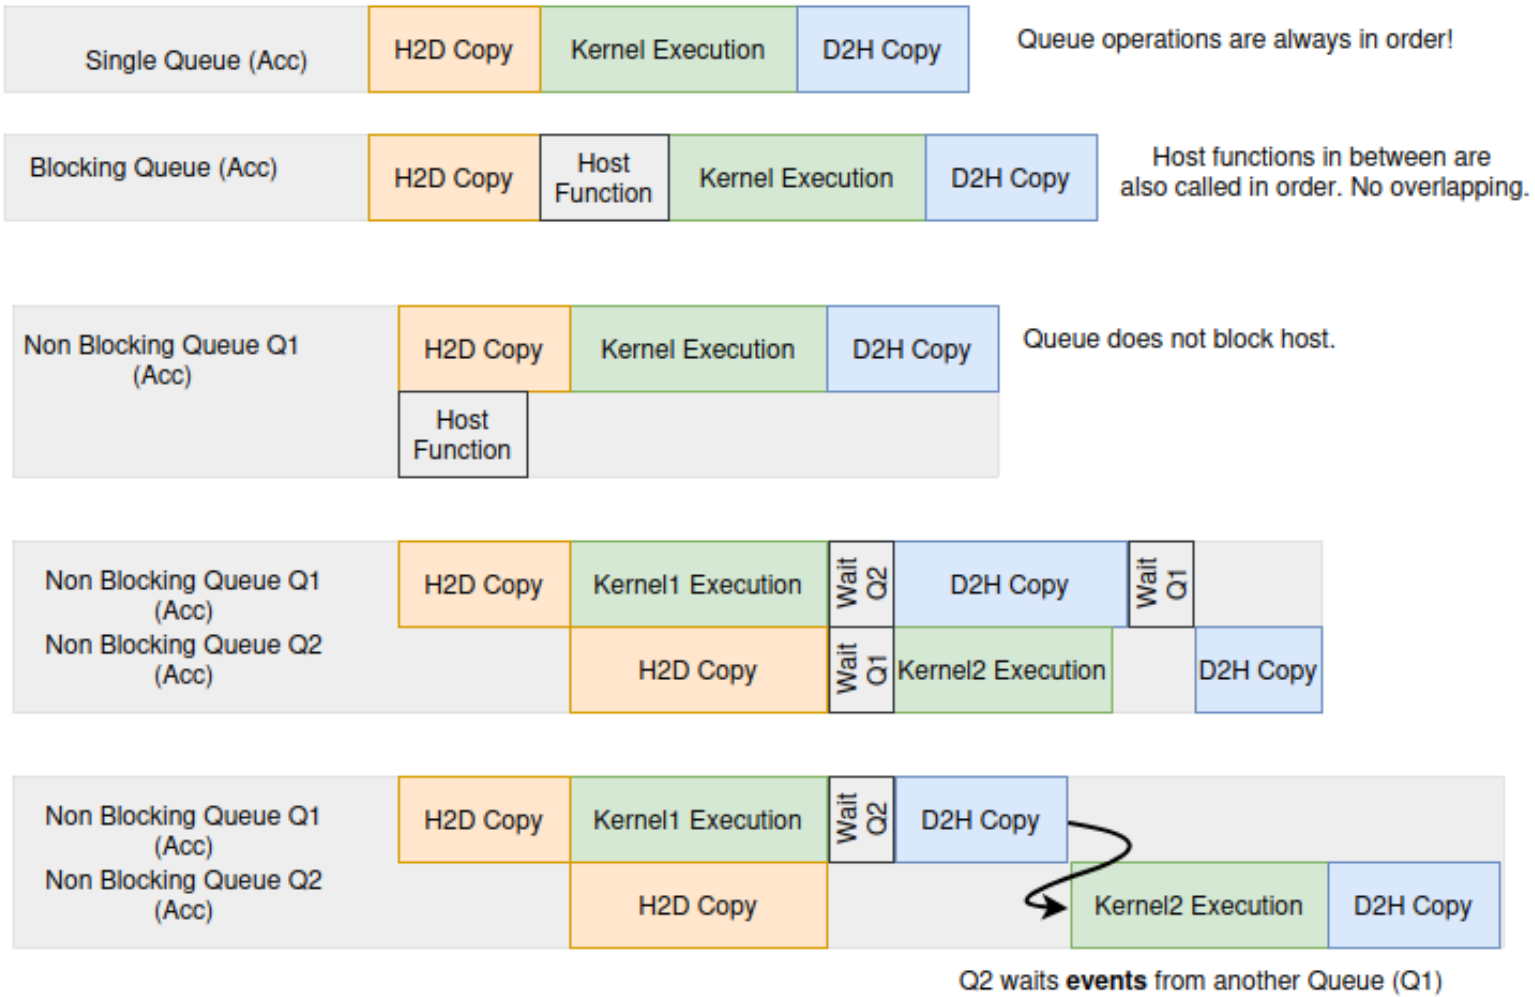
```
bool done = alpaka::empty(myQueue);
```

Queue Operations and Events

- For easier synchronization, alpaka Events can be inserted before, after or between Tasks:

```
1 auto myEvent = alpaka::Event<alpaka::Queue>(myDev);
2 alpaka::enqueue(queueA, myEvent);
3 alpaka::wait(queueB, myEvent);
4 // queueB will only resume after queueA reached myEvent
```

Some sychronization scenarios



Going over Kernel execution and copying data

- Create the queue and buffer using device

```
// Create queue,
// queue is needed for kernel execution and copies to/from accelerator
    alpaka::Queue<Acc, alpaka::NonBlocking> queue{devAcc};
    auto uBufAcc = alpaka::allocBuf<float, Idx>(devAcc, extent);
```

- Execute the kernel using the queue, the workdiv and kernel arguments:

```
    alpaka::exec<Acc>(queue, workDiv, initBufferKernel, uBufAcc.data(),
        pitchCurrAcc, dx, dy);
```

- Copy the filled buffer back to the host

```
     // Copy device -> host
     // Since buffers know their corresponding devices (host or acc) memcopy does
         not need any device variable
    alpaka::memcpy(queue, uBufHost, uBufAcc);
    alpaka::wait(queue);
```

alpaka Usability and Optimization Features

1. Use alpaka **mdspan** to set, get, pass data easily (Hands-On 5)
2. Use **Domain Decomposition**: Divide the domain into **chunks** (Hands-On 6)
3. Use **2 asynch queues** for performance increase (Hands-On 7)
4. Use **shared memory** for performance increase (Hands-On 8)

MdSpan for multi-dimensional data

Mdspan a multi-dimensional and non-owning view

- Part of C++23 standard. Can be used with C++17.
- Consists pointer, layout policy (pitch or stride info), data type, access type
- Has member functions to get/set data and to get extents
- Does not change the data, it creates a method to access to the data

mdspan as a type

```
1  // std::experimental::mdspan<ElementType, Extents, LayoutPolicy,
       AccessorPolicy>
2  int data[12] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12 };
3   std::experimental::mdspan<int, std::extents<3, 4>> spanA(data);
4   std::experimental::mdspan<int, std::extents<2, 6>> spanB(data);
5    assert(spanA(2, 3) == span2(1, 5)); //  true
```

alpaka::experimental::mdspan in alpaka

- **Mdspan Installation**
  - Set *alpaka_USE_MDSPAN* cmake variable to *FETCH* while installing alpaka
  - Alternatively, set *alpaka_USE_MDSPAN* cmake variable to *FETCH* while configuring example if it is not already set while installation

```
1  // in build directory
2  cmake -Dalpaka_USE_MDSPAN=FETCH ..
```

- **Passing mdspan to kernel**

```
1  // Host code: Allocate device memory
2  auto bufDevA = alpaka::allocBuf<DataType, Idx>(devAcc, extentA);
3  // Create mdspan views for device buffers using alpaka::experimental::getMdSpan
4  auto mdDevA = alpaka::experimental::getMdSpan(bufDevA);
5  // Execute the kernel
6  alpaka::exec<Acc>(queue, workDiv, kernel, mdDevA, mdDevB, mdDevC);
```

Kernel using mdspan instead of data pointer and pitch

Accessing data at host or at accelerator

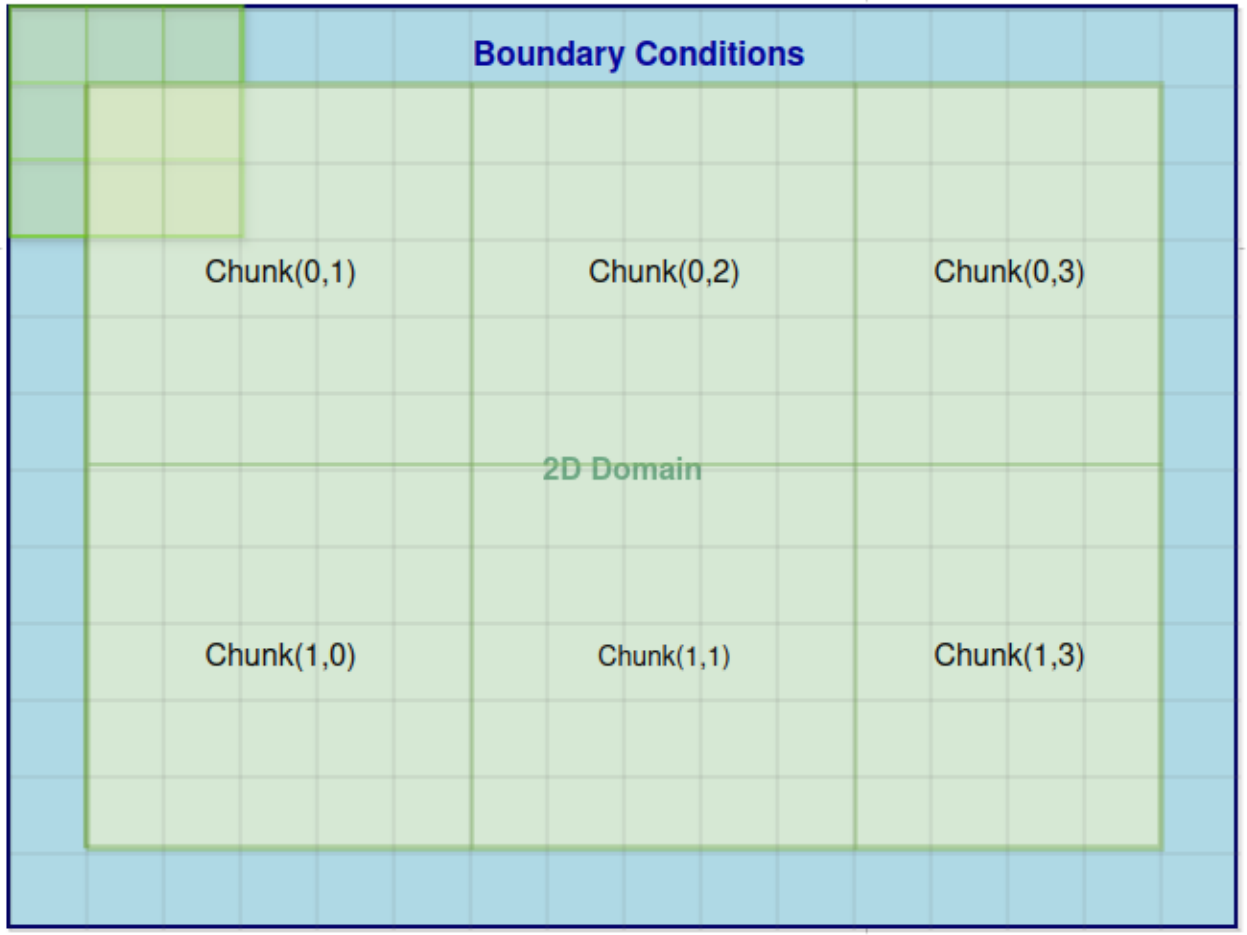
```
struct MatrixAddKernel
{   template<typename TAcc, typename TMdSpan>
    ALPAKA_FN_ACC void operator()(TAcc const& acc, TMdSpan A, TMdSpan B, TMdSpan
          C) const
    {
        auto const i = alpaka::getIdx<alpaka::Grid, alpaka::Threads>(acc)[0];
        auto const j = alpaka::getIdx<alpaka::Grid, alpaka::Threads>(acc)[1];
        if(i < C.extent(0) && j < C.extent(1))
        {
                C(i, j) = A(i, j) + B(i, j);
        }
    } };
```

```
// Update the kernel: Use mdspan instead of pointer+pitch
struct StencilKernel
{
    template<typename TAcc, typename TDim, typename TIdx>
    ALPAKA_FN_ACC auto operator()(
        TAcc const& acc,
        double const* const uCurrBuf, double* const uNextBuf,
        alpaka::Vec<TDim, TIdx> const& pitchCurr,
        alpaka::Vec<TDim, TIdx> const& pitchNext,
        alpaka::Vec<TDim, TIdx> const& haloSize,
        double const dx, double const dy, double const dt) const -> void
        {  .....
        }};
```

Hands-on Session5: Use mdspan to pass data to kernel

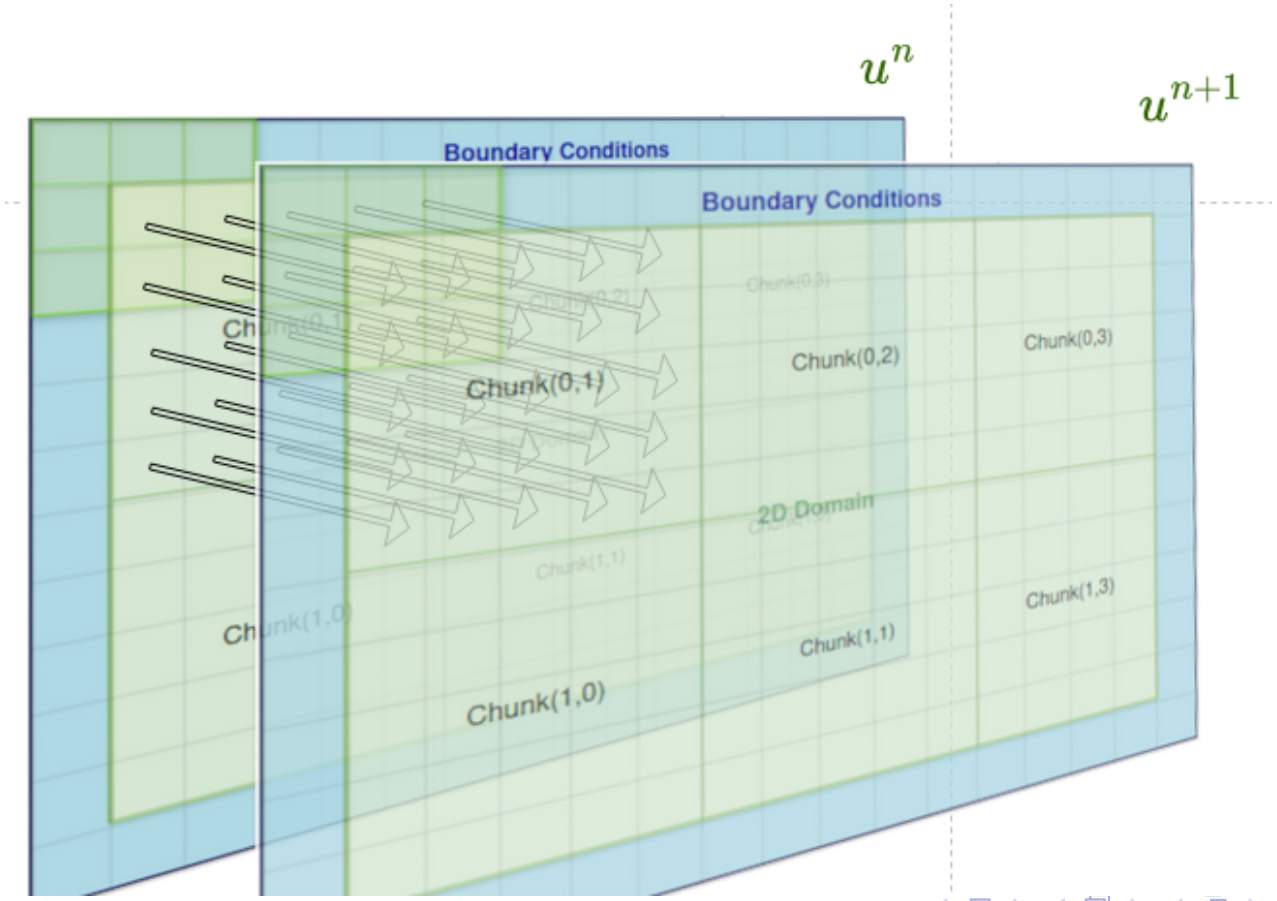
Chunk Definition

Chunk: Subdomains needed for latency management of block level parallelisation



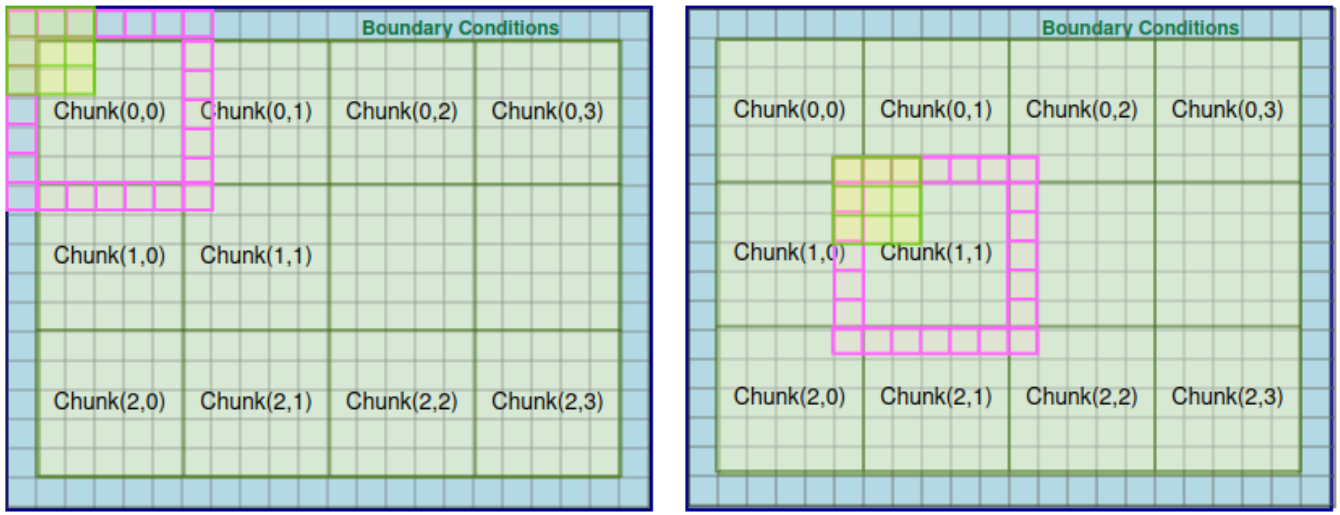
Calculation by a block of grids of stencil kernel

- Chunking is a Domain Decomposition method
- A block of threads update a chunk of heat data
- A grid of threads updates the whole domain

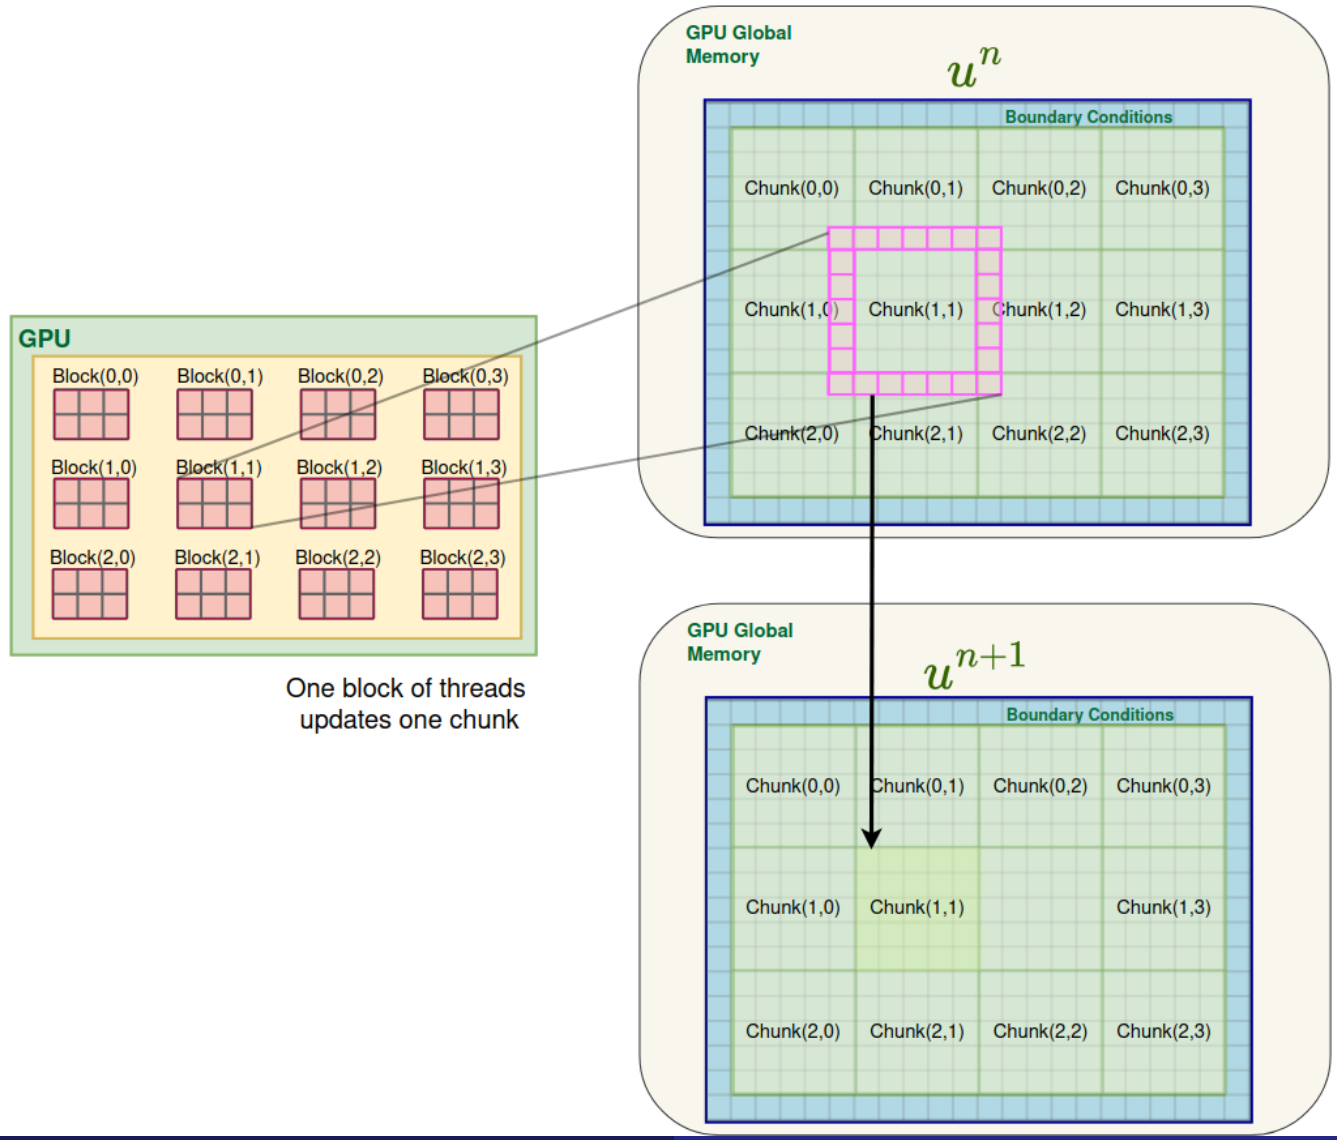


Chunks in Parallel Grid Computations

- **Halo Region around chunk:** A layer of grid cells surrounding the subdomains.
- **Halo Size:** Typically 1 for a 5-point stencil.
- Chunks-size could be larger than the block size.



A block is responsible from a chunk



Determine WorkDiv for Chunked Solution

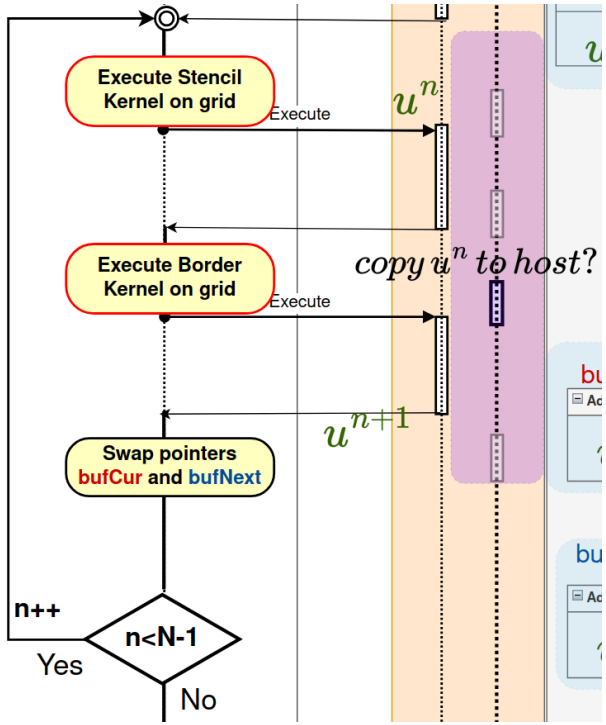
Set work division fields directly:

```
1  // Define a workdiv for the shared memory based heat eqn solution
2  constexpr alpaka::Vec<Dim, Idx> elemPerThread{1, 1};
3  // Get max threads that can be run in a block for this kernel
4  auto const kernelFunctionAttributes = alpaka::getFunctionAttributes<Acc>(
5      devAcc,
6      stencilKernel,
7      uCurrBufAcc.data(), uNextBufAcc.data(),
8      chunkSize,
9      pitchCurrAcc,pitchNextAcc,
10     dx,dy, dt);
11 auto const maxThreadsPerBlock = kernelFunctionAttributes.maxThreadsPerBlock;
12 auto const threadsPerBlock
13     = maxThreadsPerBlock < chunkSize.prod() ? alpaka::Vec<Dim, Idx>{
           maxThreadsPerBlock, 1} : chunkSize;
14 alpaka::WorkDivMembers<Dim, Idx> workDiv_manual{numChunks, threadsPerBlock,
       elemPerThread};
```

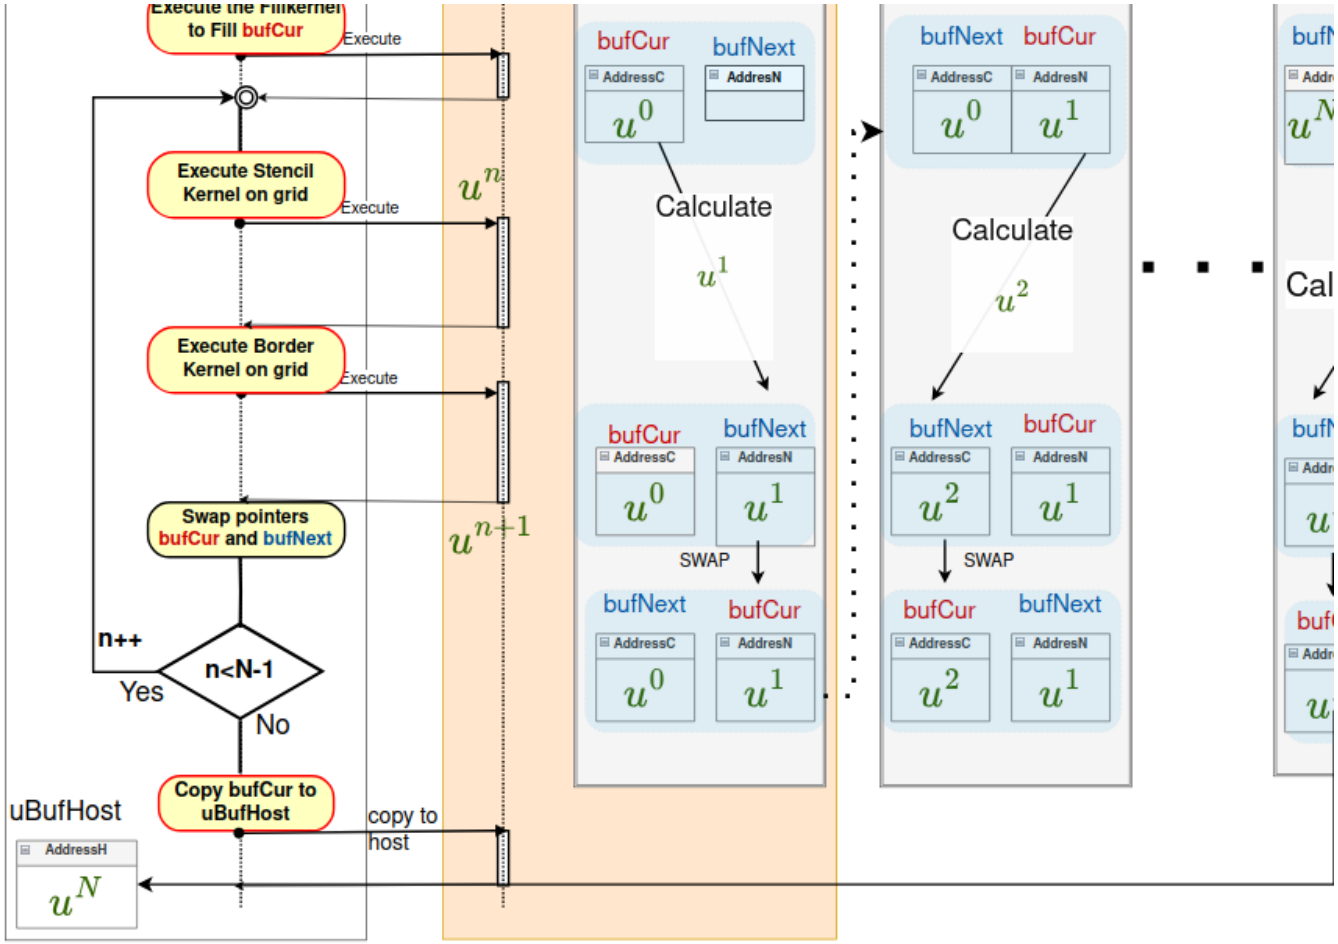
Hands-on Session6: Optimized Heat Eqn. solution by Domain Decomposition

Running 2 parallel queues: Additional queue to dump temporary results

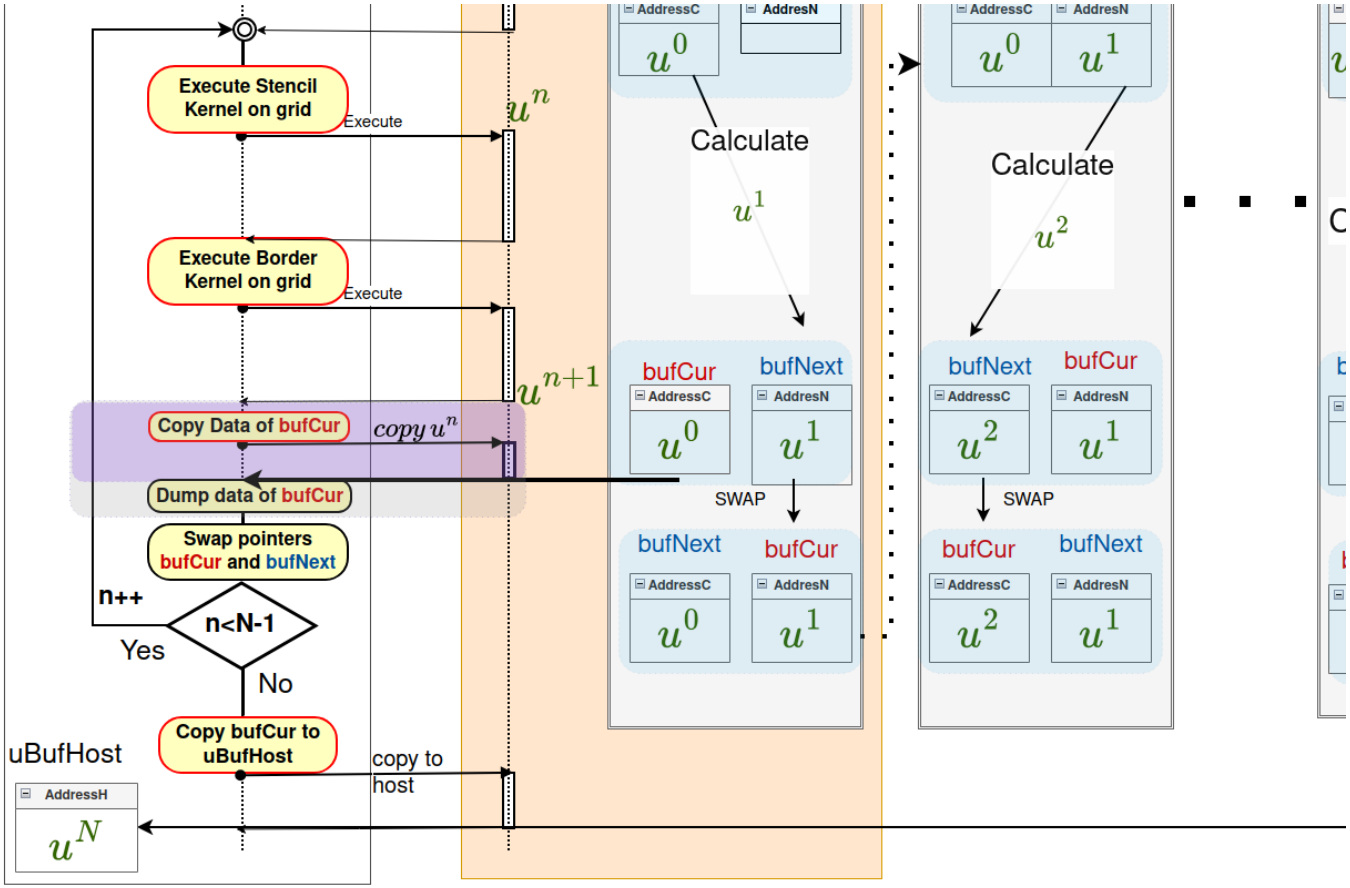
- Create an additional alpaka::queue instance at accelerator to run parallely
- The temporary heat result u^n will be copied to host from accelerator at the end of each iteration
- Copying can start while the stencil and boundary kernels are running
- In order to run 2 queues paralelly they should be a NonBlocking queues
- The copied heat data will be used to create an animation of images



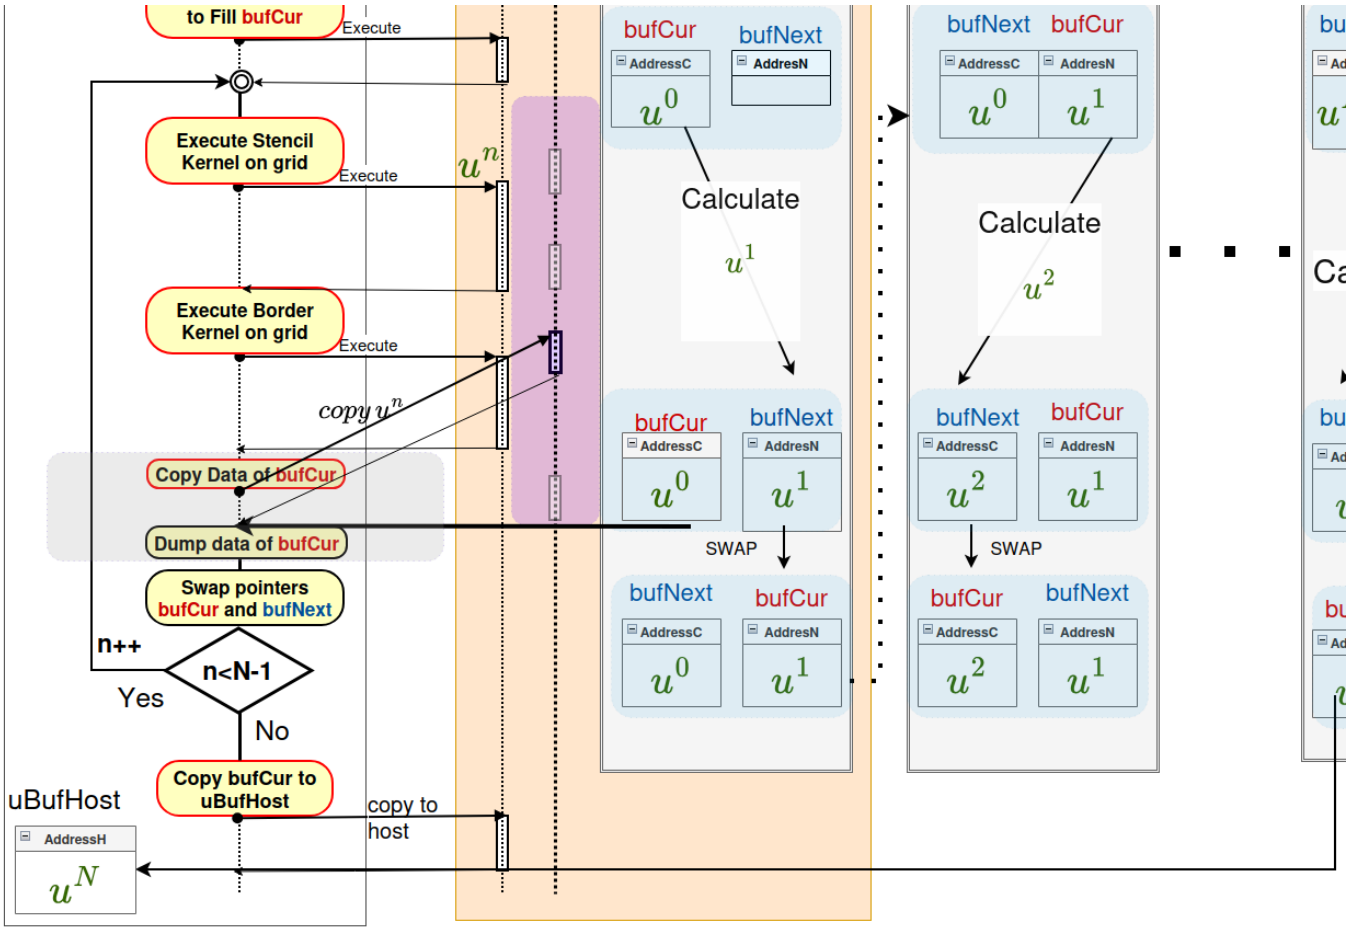
Current Loop



Copy u^n back at each iteration sequentially



Hands on 7: Copy u^n back at each iteration while kernel is running

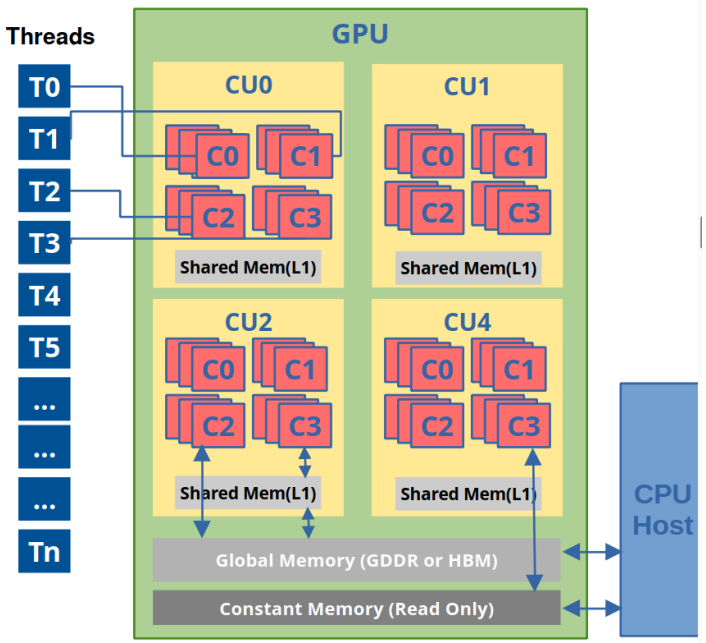


Hands-On Session7: Running 2 parallel queues to dump heat at each step

Efficient Stencil Application with Shared Memory

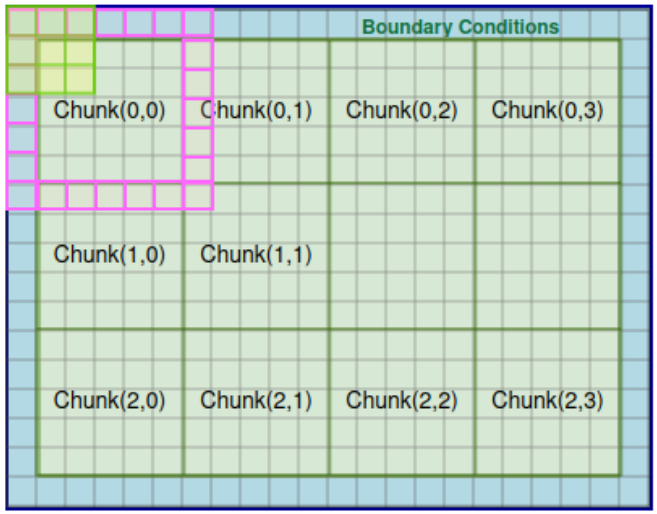
Shared Memory at GPUs

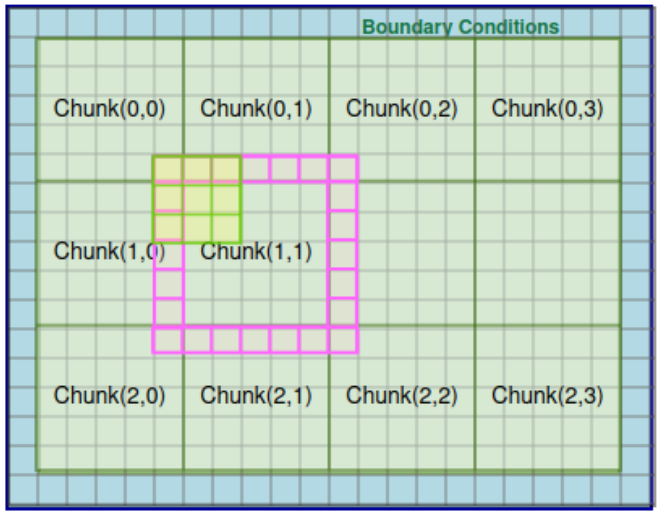
- A fast, limited-size memory accessible by all threads within a block.
- Faster than global memory. Stores data at CU (or SM).
- Shared Memory allocation can be static or dynamic.
- Filling shared memory is done by the same kernel calculating the stencil
- Threads in a block must synchronize to ensure all data is loaded into shared memory before computation begins.



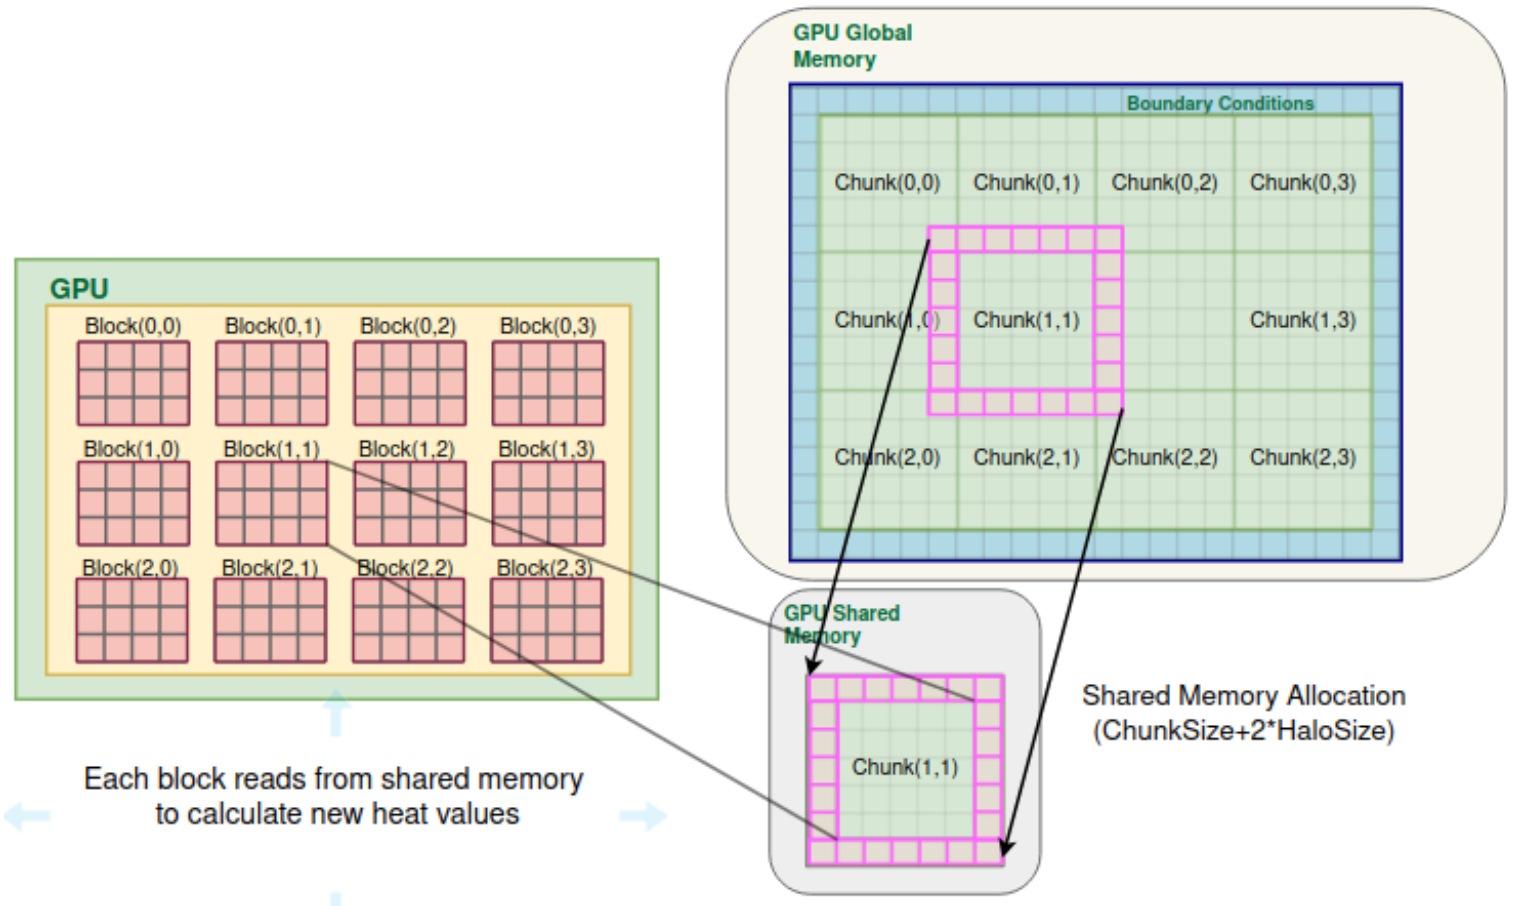
Shared memory data: chunk with halo

- **Halo Region around chunk:** A layer of grid cells surrounding the subdomains. In order to use the heat value beside the current chunk
- **Halo Size:** Typically 1 for a 5-point stencil.
- Chunks might include more than one blocks depending on the blocksize
- Kernel will install the data to shared memory then use the data from shared memory

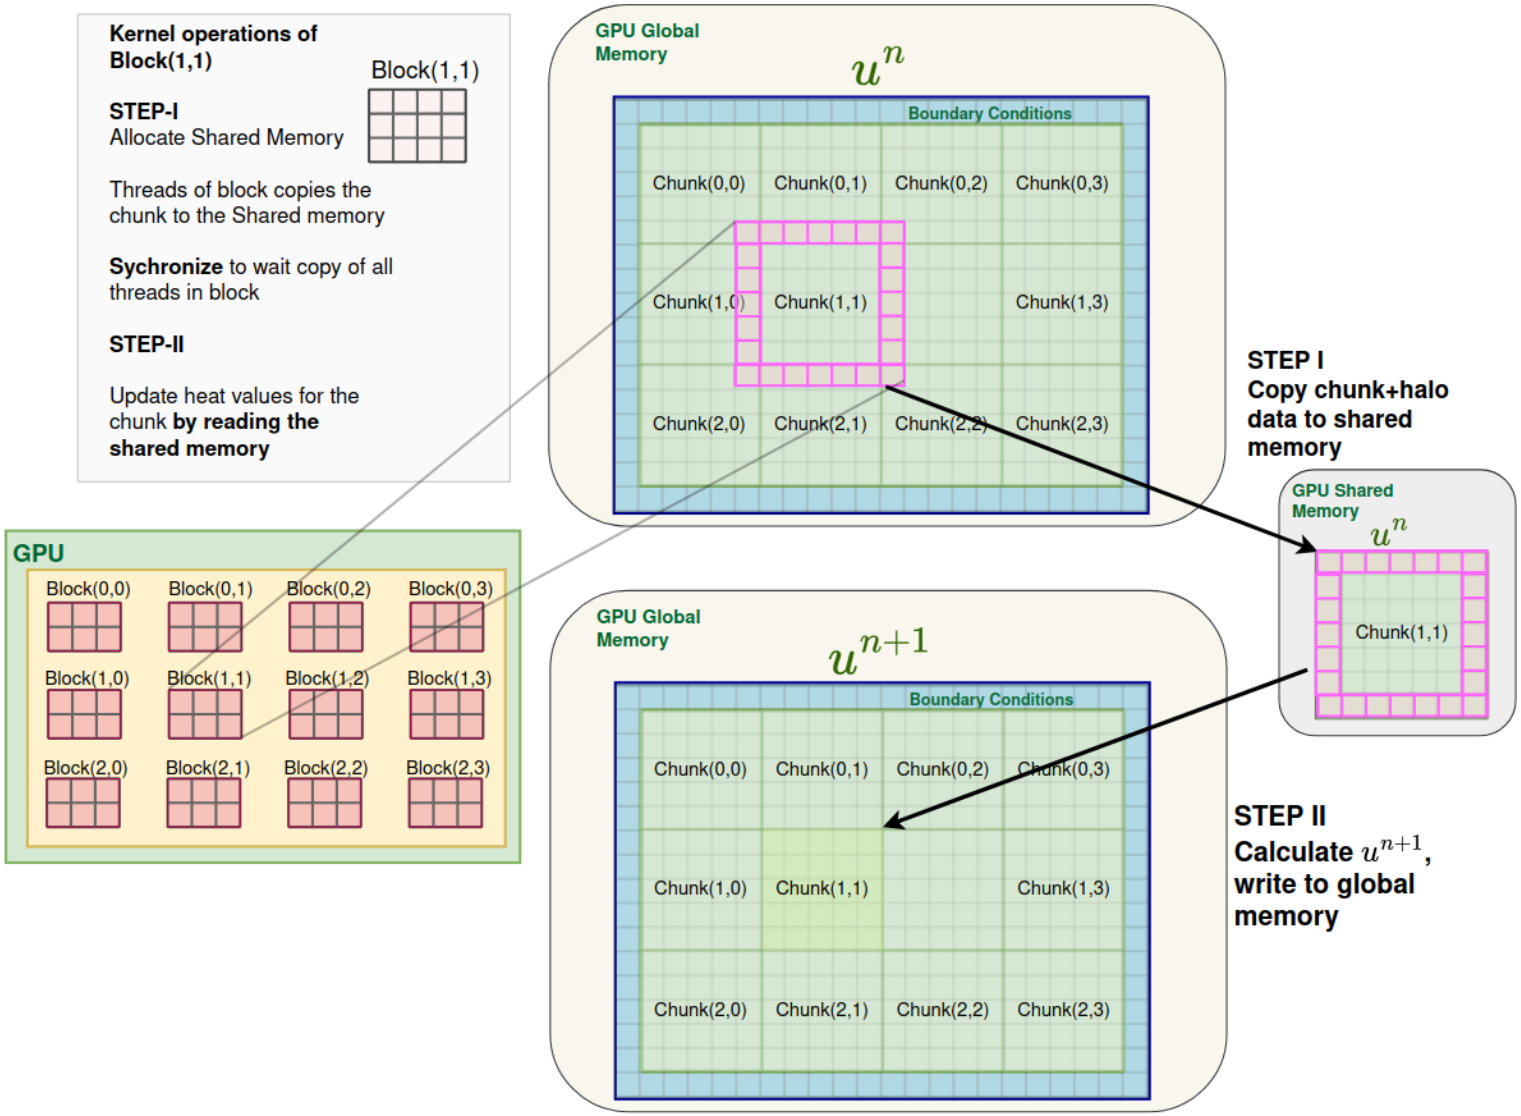




Finding u^{n+1} by using u^n from chunks at shared memory



Kernel Operations of a Block to Find u^{n+1} for block data



Hands on 8: Stencil Kernel using shared memory

- **Allocate shared memory inside kernel**

```
1       // Allocate shared memory inside kernel, this will be done only once per
            block although it is in the kernel
2       // Size is determined in compile time and is passed to kernel as a type
3       auto& sdata = alpaka::declareSharedVar<double[T_SharedMemSize1D],
            __COUNTER__>(acc);
```

- **Calculate thread index**
- **Fill the shared memory by block of threads**
- **Wait for shared memory to be filled by all block threads**

```
1       alpaka::syncBlockThreads(acc);
```

- **Calculate new heat value using the data from the shared memory**
- **Set the new heat value**

Hands-on Session8: Optimized Heat Eqn. solution by using shared memory

Conclusion: Parallel Techniques For Solving Heat Equation

- **Kernel Definition**
  - Kernel to fill a buffer in parallel
  - Stencil Kernel for calculating the next set of heat values
  - Boundary Kernel
- **Work division**
  - Getting a valid work division according to accelerator
  - Setting work-division manually
- **Allocating and Setting Memory at Host and Accelerator**
  - Using alpaka::buffer
  - Using alpaka::memcpy
- **Alpaka Structures**
  - Accelerator, Device, Queue, Task
- **Optimizations and Usability**
  - Using alpaka Mdspan
  - Domain Decomposition
  - Using Multiple Async Queues
  - Using GPU's Shared Memory

End of Alpaka Hackathon.
